01 The life science tools framework

FRAMEWORK

A product framework spanning academic research, biotech, pharma, CRDMOs and manufacturing.

Reagents

01	Recombinant proteins / antibodies
02	Enzymes / PCR and NGS reagents
03	DNA / RNA / chemical building blocks
04	Cell lines / culture media
05	Assay reagents for R&D and QC

Tests × dose per test × price

Consumables

01	Tips / microplates
02	Culture flasks / centrifuge tubes
03	Membranes / functional beads
04	Columns / chromatography resins
05	Gels / process components

Tests or batches × intensity × price

Instruments

01	Sequencers / liquid handlers
02	LC / LC-MS / mass spectrometers
03	Flow cytometers
04	High-content imaging systems
05	Cell-culture workstations

New installations + replacement + service

Use one product taxonomy; retain the scope of each market estimate.

Classify products separately from their use cases. Chromatography resins can be reused.

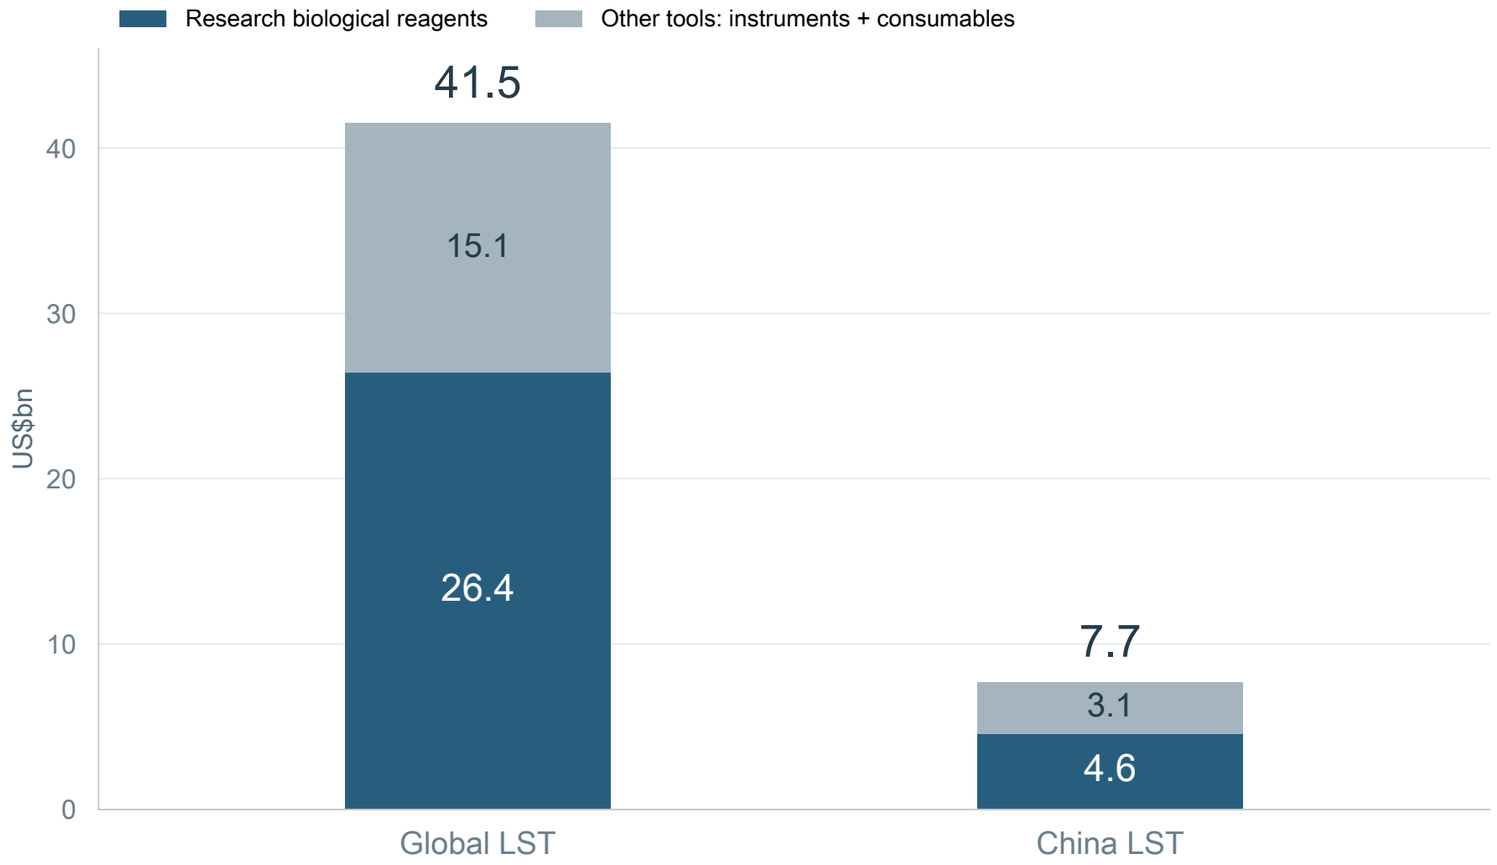

Source: supplied framework and prior product research. Existing TAMs do not automatically reconcile.

2026-10-12

02 China and global LST markets

HISTORICAL

2025 historical estimates from one F&S study; this is a defined market scope, not a universal LST TAM.

China / global market

18.6%

7.7 / 41.5
Same-scope historical estimate

Broader research and production markets require a separate scope reconciliation.

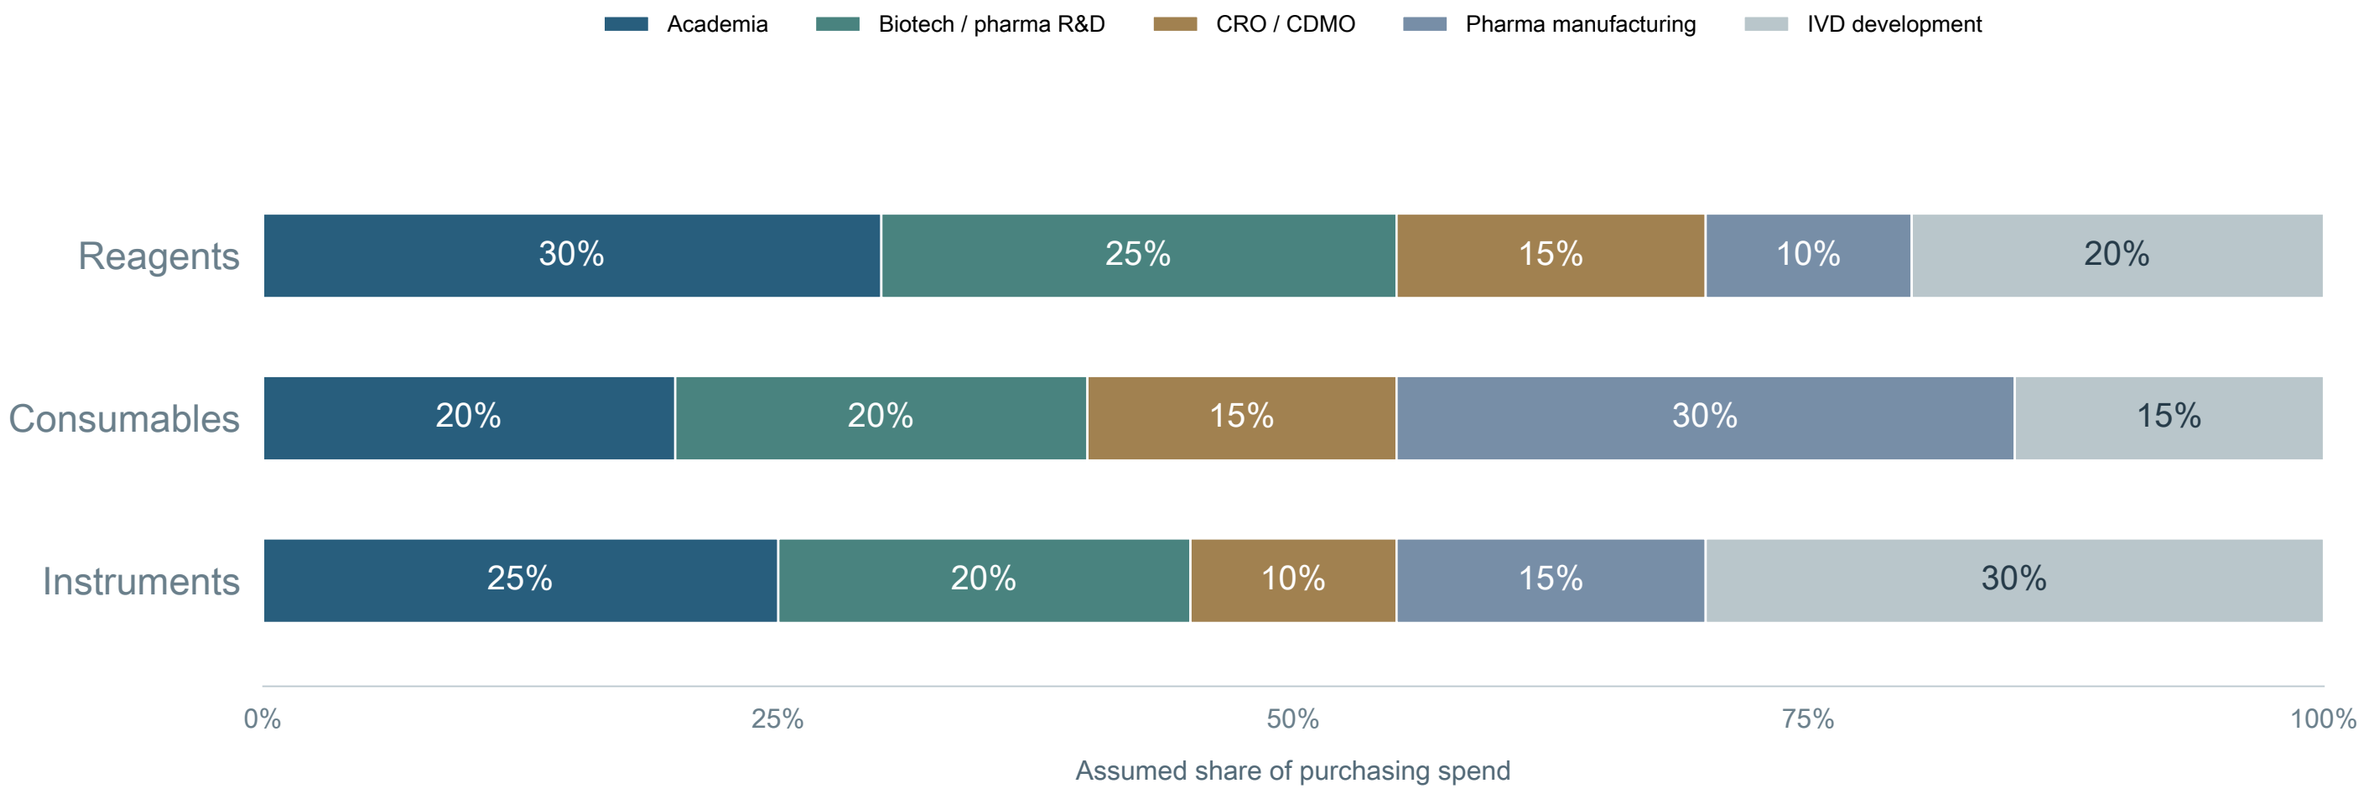

Other tools are the residual. Comparable instrument and consumable splits were not separately available.

Source: ACROBiosystems HKEX application, 30 Sep 2026, printed pp. 65 and 67; links in SOURCES.md.

03 How downstream demand differs

ILLUSTRATIVE

Direct purchasing differs by product basket. These supplied assumptions sum to 100% for each row.

Reagents: more research exposure in this scenario

Consumables: more production exposure

CRO/CDMO purchases are separate from pharma-owned production. Hospitals are not separately modeled.

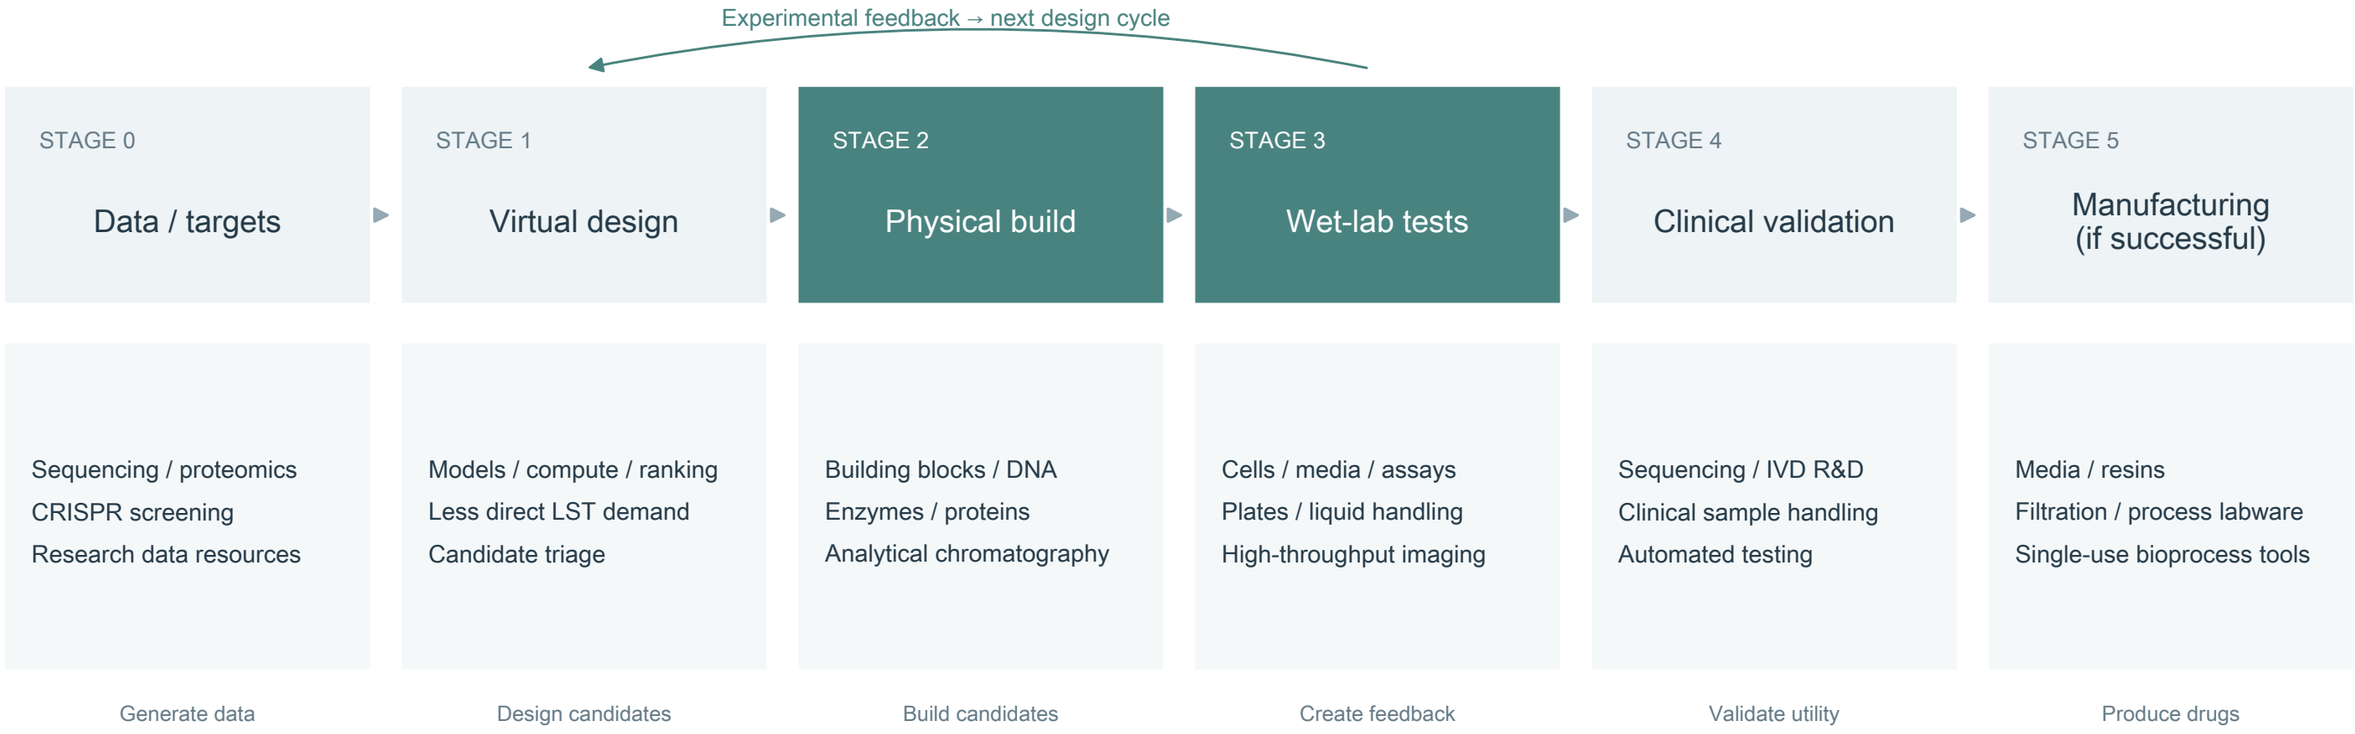

Source: illustrative shares in the supplied manuscript; these are not measured customer shares.

04 AI discovery and its LST touchpoints

MECHANISM

AI candidates need physical construction and experimental feedback. Orders depend on funded projects.

The most direct potential uplift comes from building and testing candidates.

Stages 2–3 have more direct exposure. Clinical and manufacturing demand face attrition and time lags.

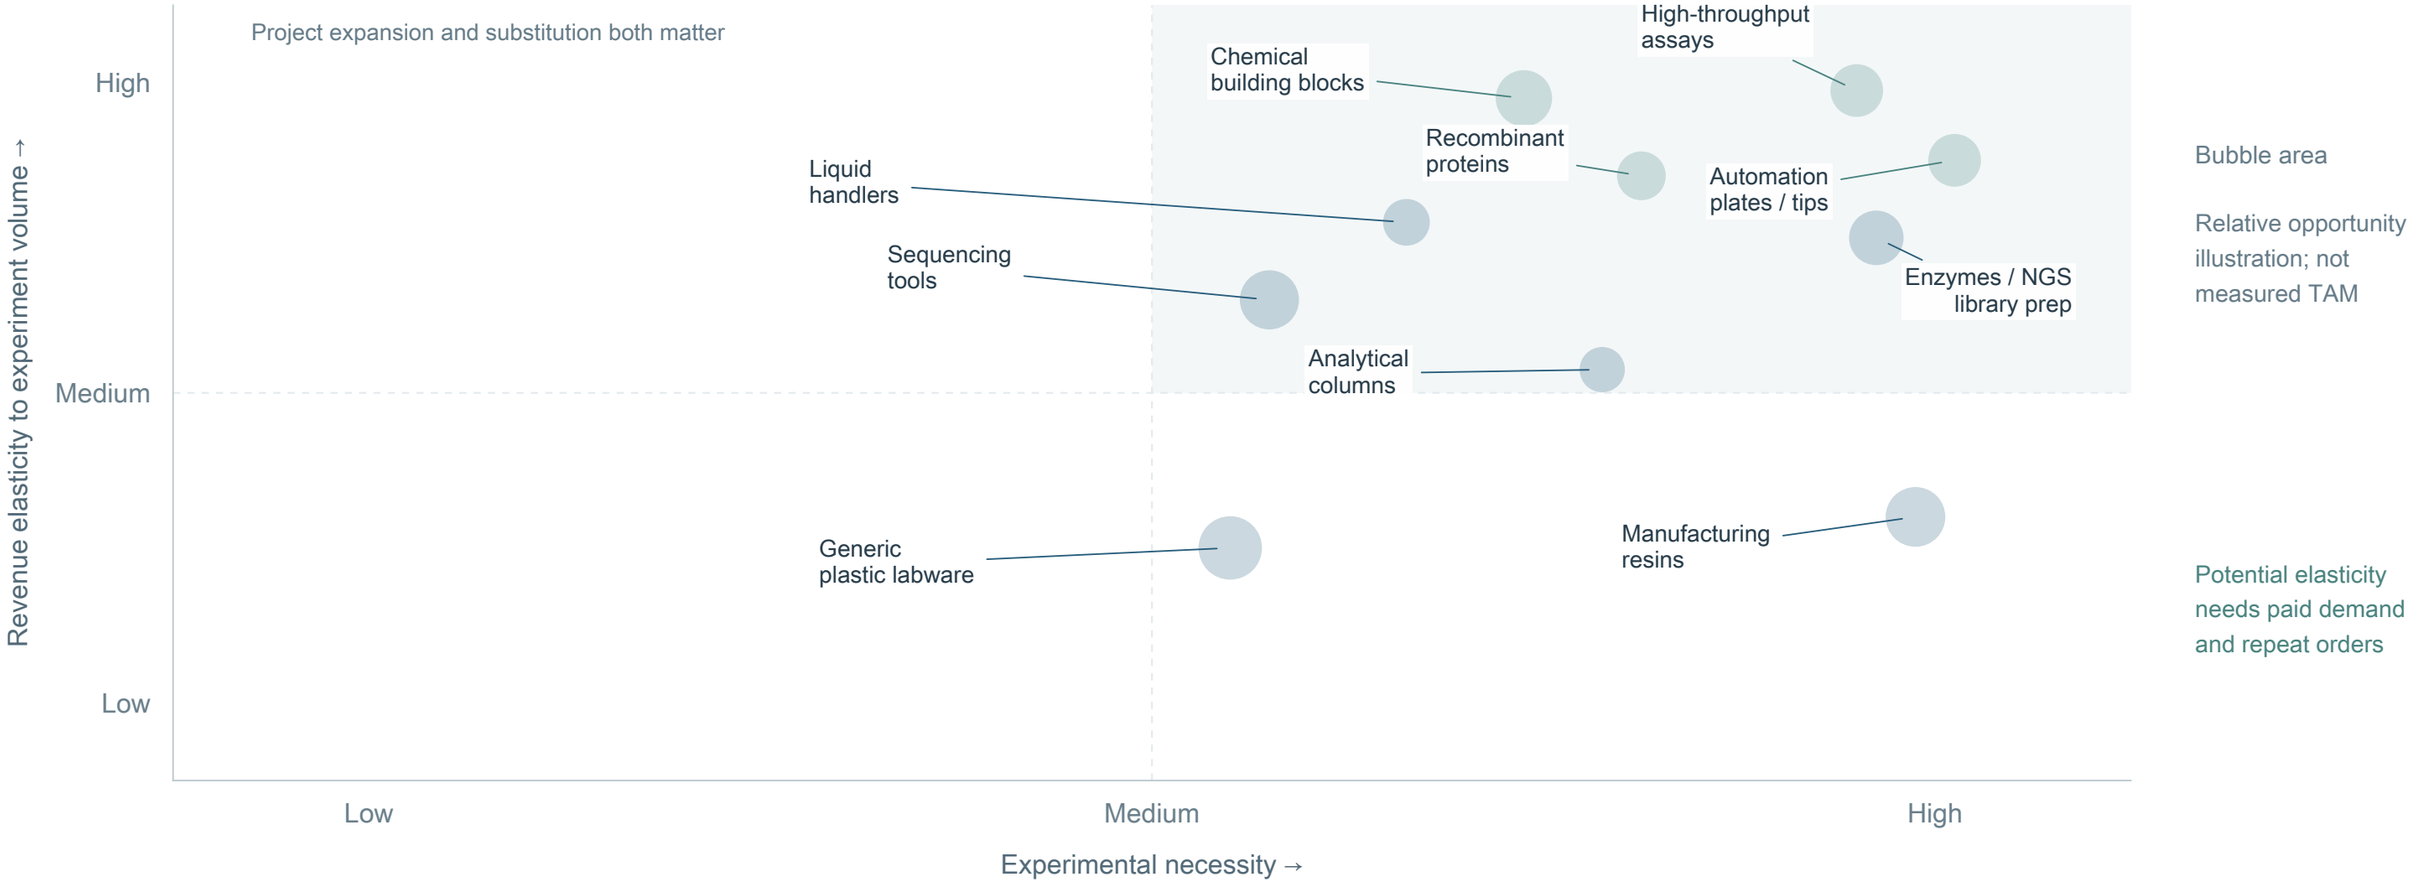

Source: supplied framework and product-use research. Arrows describe a mechanism, not realized orders.

2026-10-12

05 Which tools have more demand elasticity?

HYPOTHESIS

Positions and bubble areas are qualitative research judgments, not measured scores or additive TAMs.

Net demand also depends on consumption intensity, prices, project attrition and technical substitution.

Source: supplied framework and analyst assumptions. Edit positions and relative areas in data.json.

2026-10-12

06 More experiments, less material per experiment

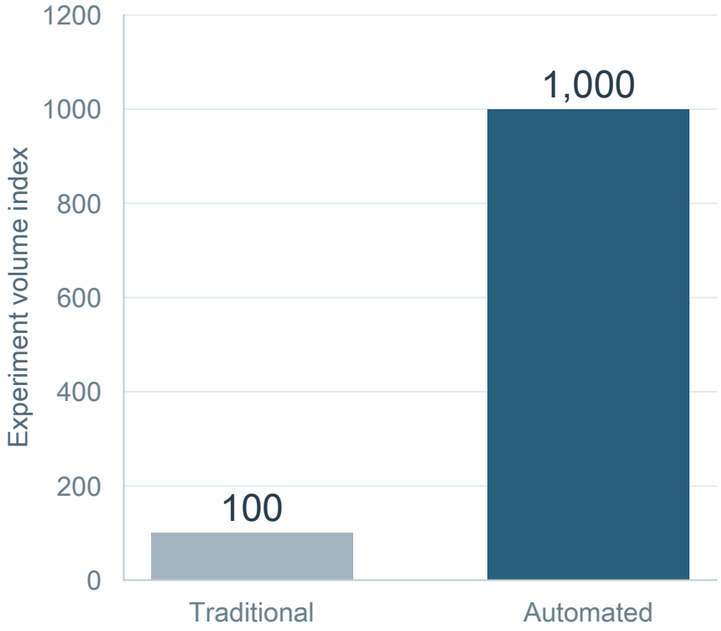

SCENARIO

Traditional: 100k tests, 96 wells, 100 µL/test. Automated: 1m tests, 1,536 wells, 5 µL/test. Base = 100.

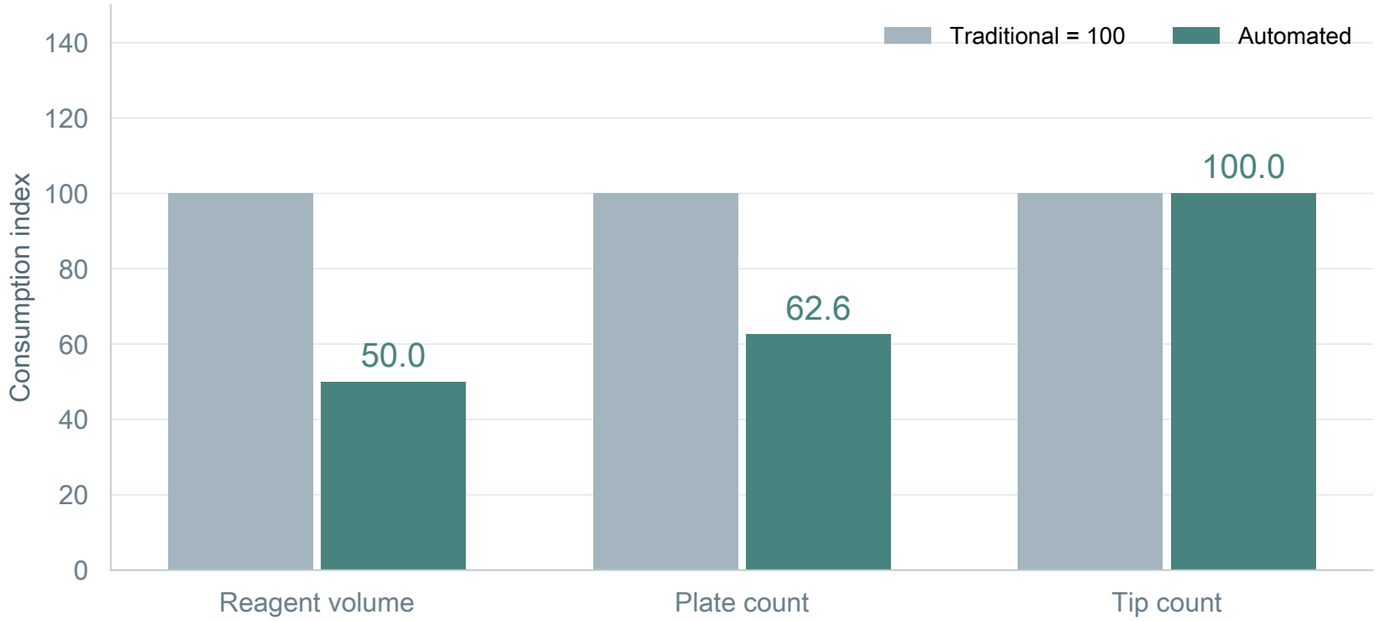

100k → 1m experiments

Reagents: 10 L → 5 L · Plates: 1,042 → 652 · Tips: 100k → 100k (assumed)

Experiment volume: 10×

Consumption can fall or remain flat

Experiment growth does not imply proportional purchasing growth.

Y-axis scales differ. Full plates, no dead volume or control wells; tips fall from 1 to 0.1 per test. ASP excluded.

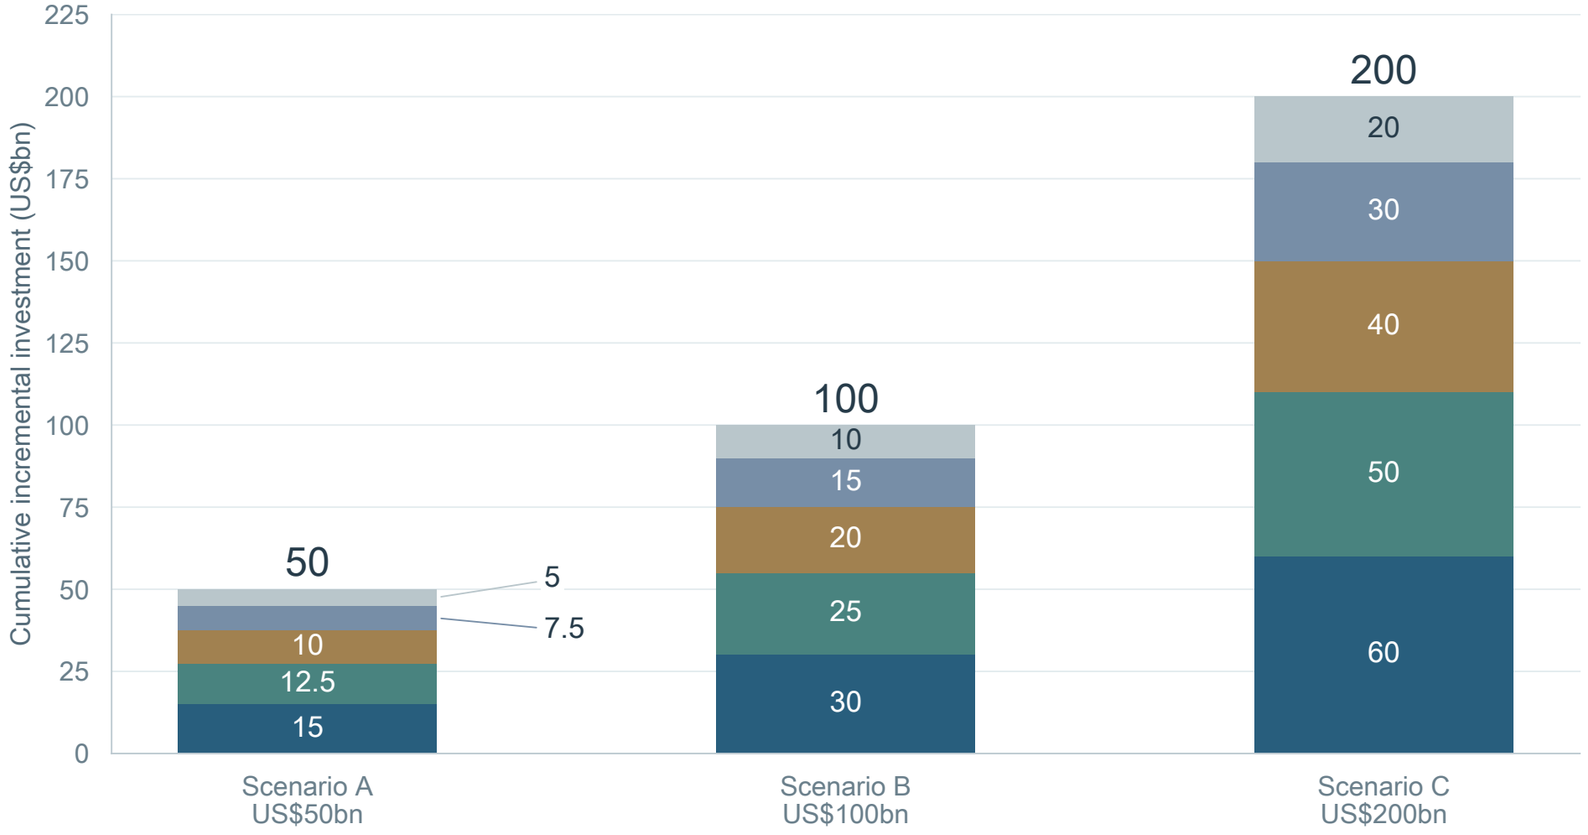

Source: supplied scenario and analyst calculation. Test definition and plate utilization affect the result.

07 Illustrative AI-driven investment scenarios

SCENARIO

US$50bn / 100bn / 200bn are illustrative cumulative investment pools; no time horizon is specified.

- Research equipment / automation
- Research reagents
- Research consumables
- Manufacturing bioprocess tools
- Services / other

Build phase → installed equipment

Operate → recurring purchases

Manufacturing needs drug output.

Allocations: 30% / 25% / 20% / 15% / 10%. Research and manufacturing buckets are mutually exclusive.

Source: supplied scenario and allocation assumptions. These are not realized funding, orders or annual TAMs.

2026-10-12

08 Potential supply constraints over 12–24 months

HYPOTHESIS

Relative expansion and qualification constraints over 12–24 months; current shortages are not established.

Track lead times, stockouts, qualification, yields and prices. Manufacturing resins have a longer demand lag.

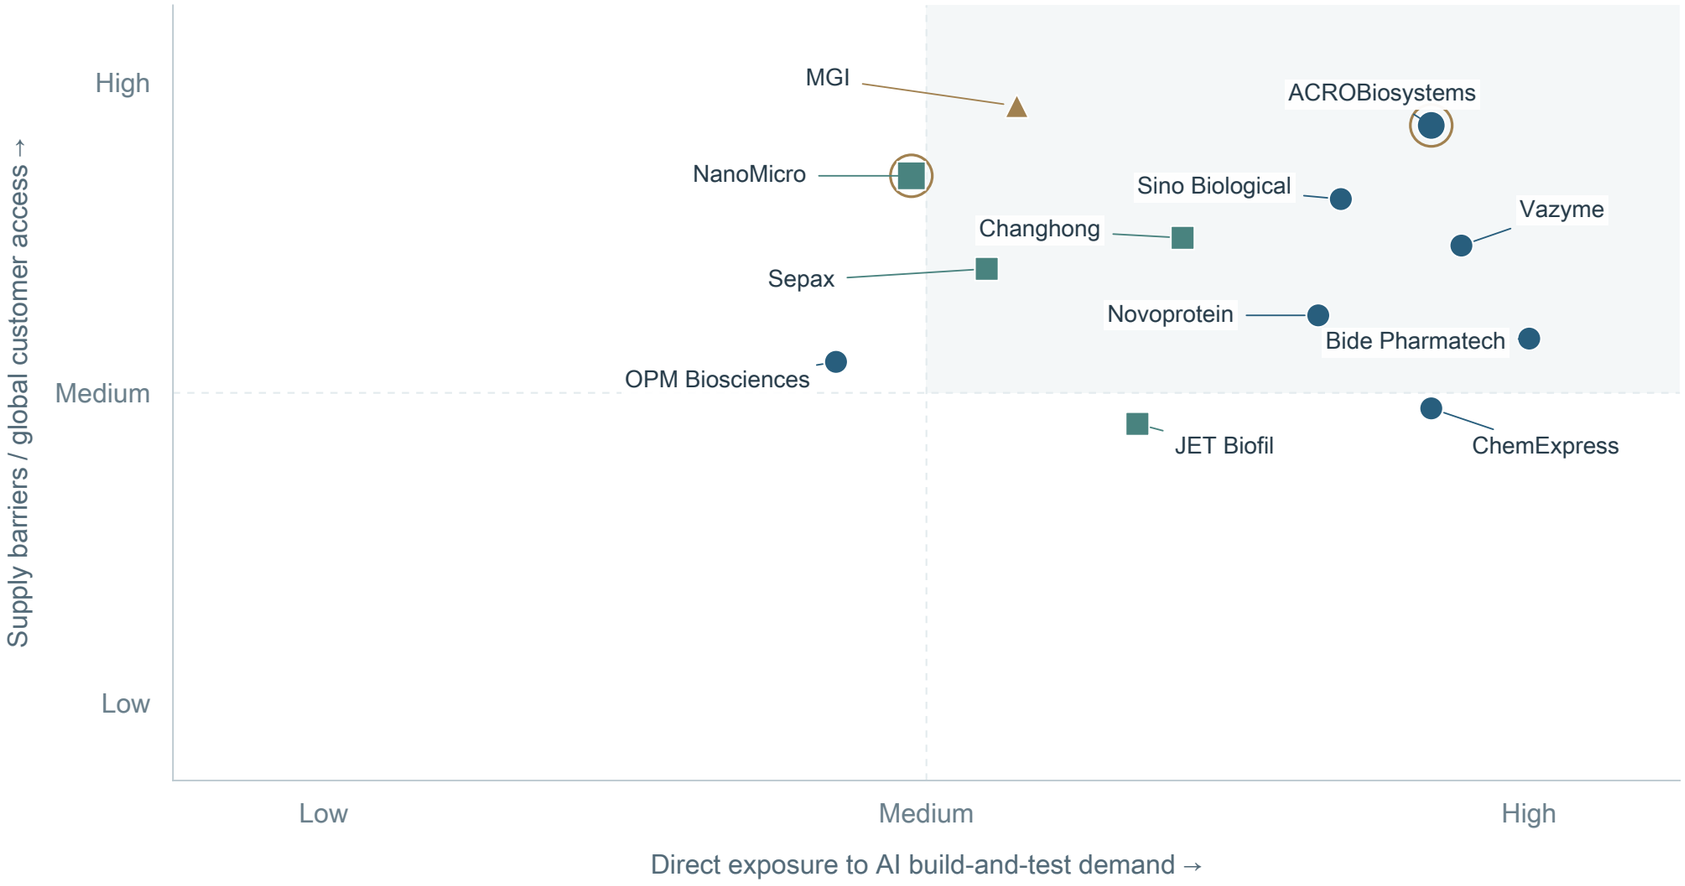

Source: supplied framework and analyst hypotheses. Technical barriers do not prove a capacity bottleneck.

2026-10-12

09 Mapping Chinese listed LST suppliers

HYPOTHESIS

Product exposure to AI build-and-test stages; positions do not measure AI revenue share or investment rank.

Reagents

Proteins, enzymes, blocks, media

Consumables

Labware, columns, resins

Instruments / platforms

Sequencing and automation

Two different demand pathways

ACRO: expression / functional assays
NanoMicro: purification + scale-up

Axes are qualitative judgments. Qualification, global customer access and paid orders still require evidence.

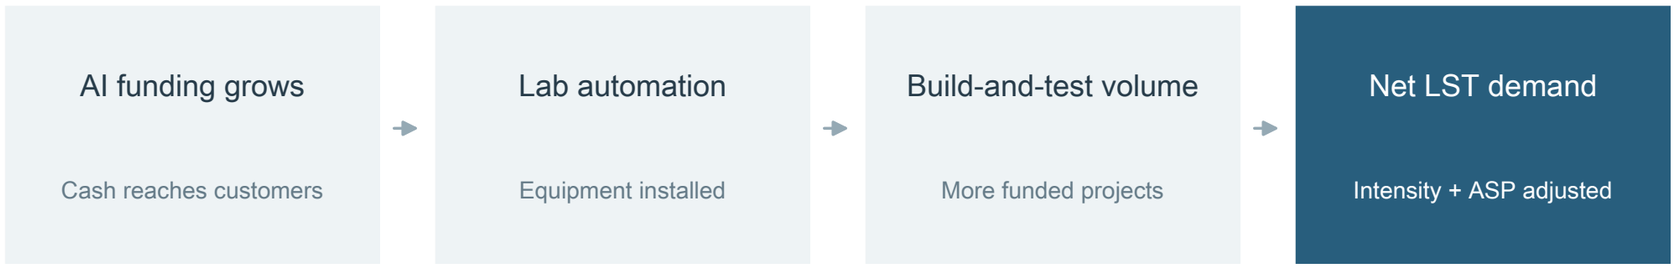

Sources: company filings and official product catalogs. Product rationale and assumptions are in data.json.

2026-10-12

10 From AI funding to LST shareholder returns

THESIS

Funding starts the chain. Projects, consumption, supply, market share and cash returns determine the outcome.

Direct demand

Assays, automation labware and chemical building blocks

Supply constraints

Specialty plates / components
Expansion limits need evidence

Listed candidates

ACRO, Vazyme, Sino, NanoMicro JET, Changhong and others

Evidence is needed at each step

Customer budgets → orders / repeat purchases → net consumption → utilization → company share → recurring profit / free cash flow → growth priced into the stock

Experimental relevance ∩ Evidenced supply constraints ∩ Global customer access

Seek experimental relevance, evidenced supply constraints and global access; test the valuation hurdle.

Source: supplied framework and prior company research. Capital announcements are not LST orders.
